Physiotherapy advice following heart transplant

Patient information guide
Stages of Physiotherapy

Your physiotherapist will be in to see you the day after your operation. Exercises will be gentle at this point consisting of deep breathing and limb movements to keep your joints supple. These are very important to keep your chest clear and strengthen your muscles which may have been weakened while you were unwell.

When you are breathing independently and your condition is stable you will be helped into a chair by your physiotherapist. You may feel dizzy at first however this will soon settle.

Because of the drugs you are taking to suppress your immune system you will be initially asked not to leave your room. This is to minimise the risk of you picking up an infection. A minor illness which normally makes you feel a bit unwell could make you seriously unwell at this time. Physiotherapy will consist of exercises in your room, marching on the spot, bed exercises and exercise pedals. Your physiotherapist will devise an exercise programme for your needs. You are permitted to leave your room when your biopsy results are satisfactory. Your first biopsy is approximately 7-10 days after surgery.

At this time your exercise programme will be continued in the physiotherapy gym which has facilities such as a treadmill, exercise bike and weights. You will be able to visit the gym daily and work under the supervision of your physiotherapist.

Your physiotherapy will continue after your discharge as an outpatient at your local hospital as part of a Cardiac Rehabilitation programme where you will be offered a tailored exercise program to suit your own needs. Record your progress and set goals for your recovery.
Things to consider when exercising

**Slow heart rate response.** Previously your heart relied on its nerve supply to increase your heart rate in response to exercise. Your transplanted heart has no nerve supply. Initially the heart pumps harder in response to the increased blood flow caused by your muscles contracting. It also relies on hormones circulating in the blood stream to receive instructions on how quickly it should be beating. These hormones gradually increase in amounts during exercise, however this takes several minutes. Overall the response of a transplanted heart is a lot slower than a normal heart.

**Drugs.** There are side effects of your medication which may affect your exercise capacity. Calf pain occurs in 15% of patients taking cyclosporin. Long term steroid use can cause muscle weakness, obesity, and osteoporosis. Tremor is also a common side effect of both drugs. Muscle weakness, obesity and osteoporosis are all aided by varying types of exercise. Your therapist can tailor an exercise program to target a specific concern or problem that you have.

**Lack of fitness.** Most patients are inactive for long periods before their surgery. This will result in large losses in muscle strength and flexibility. The ability of your new heart to pump blood will also be reduced due to the loss of nerve supply.

**Warm up.** It is vital that you allow a warm up period of around 10 minutes before exercising. It takes around eight minutes for your body to produce the hormones that speed up your heart rate. This time will also allow for increased blood flow to your muscles and to improve their flexibility reducing the chance of injury.

**Difficulty of exercise.** The goal of your exercise program is to strengthen your heart muscle. This is done by gradually and gently increasing the work for your heart for short periods up to five times a week. Exercise that strengthens your heart muscle is called aerobic exercise.
It is not possible to use your heart rate as a guide as it is no longer regulated by your nervous system. To measure your exertion levels we advise using the Borg Scale. This scale measures breathlessness and is explained on the back page of this booklet. You should also discuss this with your physiotherapist. Aim to work between 12 and 14 on the Borg Scale.

**Strengthening.** You should not start arm exercises until three months after your transplant. This is the time that your breast bone takes to knit back together and fully heal. It is common for patients to lose large amounts of muscle particularly if you have been waiting a while for your transplant. Strengthening exercises are the quickest way to replace this muscle. You can begin strengthening your legs as soon as you get home. Before you begin it is very important you are taught how to do exercises safely by your physiotherapist.

**Cool Down.** This is the opposite of your warm up. A gradual reduction of exercise intensity is necessary to allow your heart rate to slow gradually and allow levels of exercise hormones to reduce.

**Types of exercise**

The best form of exercise in the first eight weeks after your operation is walking. Slowly increase the pace and distance you are covering each time. Strolling may not be enough you may have to stride out and use your arms. You can also work on a static exercise bike during this period however leave cycling on a bicycle until your sternum has healed. Record your progress and set realistic goals with your physiotherapist.

After eight weeks you can begin playing sports using your arms such as golf, bowling, exercise classes and badminton as long as you are not in any discomfort. Leave higher impact sports such as tennis, squash and team games until three months after your surgery. Your physiotherapist will be able to assess your suitability for returning to these sports.
What if I have a period of rejection?

If you suffer a period of rejection you should not exercise but can carry on with other daily activities as normal. Gradually start again when you are feeling better and have had a normal biopsy.

Exercise in the community

When you go home you will be referred to your local hospital for cardiac rehabilitation beginning approximately six to eight weeks after discharge.

Once you have completed cardiac rehabilitation you can discuss with your therapist whether it is suitable to join your local gym where you can work on your own or take part in exercise classes. If you take part in classes please make sure that your instructor is a qualified fitness professional. Let the instructor know about your surgery and any ongoing problems you may be having. They may not have come across a heart transplant patient before so bring along some information for them or ask them to contact the physiotherapy department at the Golden Jubilee National Hospital. Remind them that the normal monitoring process may not be accurate and the Borg Scale is generally used.

Finally........regular exercise will

- Strengthen your new heart
- Reduce damage to your new heart - particularly if heart disease was the cause of your previous problems
- Help you feel more confident
- Help with weight control
- Reduce blood pressure and cholesterol
- Reduce stress and chances of osteoporosis
- Increase your energy levels
- Assist your body’s ability to fight infection
- Make you feel and look younger and healthier
